ABSTRACT

Pakistan has the potential to produce renewable energy, which is critically needed in areas such as Korangi, a district in Karachi, Pakistan, that faces major challenges, such as rapid urbanization and pollution. In this study, Google Earth Pro was used to analyze solar panels' location using historical data from 2017. It was found that there are fewer solar panels in the industrial belt of Korangi. Korangi is situated in the southern part of the country, approximately 24.8 degrees north of the equator at latitude, which is relatively close to the equator, contributing to the high level of solar radiation and warm climate. Thus, this area is considered favorable for solar panels or energy production and 95 sampling locations were selected for the pollution assessment. Of these, 52 were those sites where solar panels are installed, and the remaining were at residential and commercial locations. Compared to 2017, the variables assessed in the existing research's pollutants are higher in the non-industrial zone (residential and commercial localities) for 2023. Air Quality Hazard zones are also found along the areas of conventional power generating plants. This study concludes with recommendations for city planners, policymakers, and energy professionals to frame appropriate strategies for Korangi-Karachi; which has implications for other regions in the country with potential for solar energy.

Keywords: Solar panel, Renewable energy, Green energy, Sustainability, GIS, Environmental pollution.

INTRODUCTION

Pakistan has the potential to produce renewable energy. According to the World Bank, Pakistan's current electricity demand would be met using just 0.071 percent of solar photovoltaic (solar PV) power generation (World Bank, 2020). On average, Pakistan receives approximately 1000 watts per square meter (W/m²) of solar energy for about 6 to 7 hours daily (Ulfat et al., 2012). The annual solar irradiance varies in different cities, some areas receive up to 4,459.15 kWh/m² annually, while others may receive as little as 7.65 kWh/m² (Adnan et al., 2012). The reliance on thermal sources, specifically oil and natural gas, poses numerous financial and environmental challenges for the country. Despite this, Pakistan utilizes oil, natural gas, and coal as fuel sources, and is largely based on thermal power plants to generate electricity. Thermal power, as of January 2024, accounts for around 62% of the total installed production capacity, transforming to about 28,811 MW out of a total capacity of 46,035 MW (Global Data, 2023). Radiation can also vary by geographical location, for instance, Islamabad, Karachi, and Lahore have been monitored for solar energy potential. Empirical models developed to estimate solar radiation on the behavior of local climate conditions reveal that Pakistan has various solar energy environments (Aggarwal, 2021).

Pakistan could generate over 2.9 million MW (megawatt) of solar energy. Despite having great potential in producing renewable energy using solar power, Pakistan has yet to fully tap this resource, contending with severe energy shortages, depending mainly on non-renewable sources. The energy shortage is projected to reach 50,000 MW by 2022, requiring urgent incorporation of renewable sources like solar power into the national grid (Latif et al., 2018). A boom in industrial activities in this area has been seen, with around 4,500 industrial units operating in the Korangi industrial area alone (Khalid et al., 2017). Korangi experiences high concentrations of particulate matter (PM10 and PM2.5), sulfur dioxide (SO2), nitrogen oxides (NOx), and carbon monoxide (CO). These pollutants go beyond the levels set by the Sindh Environmental Protection Agency (SEPA) (Idress et al., 2023).

The Korangi power plant, particularly the Korangi combined cycle power plant, contributes to pollution, due to its reliance on fossil fuels for electricity generation. Korangi as a gas-fired power plant which emits pollutants such as sulfur dioxide (SO2) and nitrogen oxides (NOx), and are known to create environmental problems. While the production of solar panels involves energy-intensive materials and hazardous chemicals, the overall environmental impact is mitigated by the fact that solar energy systems can generate clean energy for up to 30 years, offsetting the initial energy and resource inputs within 1 to 4 years. Thus, regardless of the environmental costs associated with manufacturing and disposal, solar power remains a more sustainable and less polluting option compared to conventional electric power plants (U.S. Energy Information Administration, 2024). Karachi's air is highly contaminated with a high value of Air Quality Index (Kausar et al., 2024). Korangi district in Karachi is the most affected area, mainly due to the concentration of PM^{2.5}. The Sindh government has announced plans to provide solar systems to 200,000 households across the province, including 50,000 homes in Karachi. Access to low-cost loans and financial incentives can facilitate solar adoption (Haq et al., 2020).

Research Problem

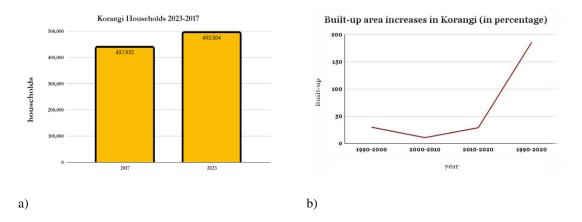

An increased susceptibility of the country's dependence on energy imports puts upward pressure on electricity prices for consumers and enhances exposure to global commodity price volatilities (Voluntary National Review, 2019). Pakistan has been facing a shortage of between 3000 MW and 6000 MW within the supply and generation, subsequent in many hours of load-shedding. With Karachi facing frequent power outages and reliance on fossil fuels, scholars argue that the transition to renewable energy has the potential to reduce carbon emissions and improve energy security (Kalhoro et al., 2019). However, some barriers include poor rooftop utilization for solar panels, limited access to real-time solar radiation data, and encounters posed by urban density and planning (Kabir et al. 2018). Existing studies underline the critical

role of leveraging Geographic Information System (GIS) tools and satellite data to provide actionable visions for urban planners and other stakeholders to advance solar adoption in Karachi (Shahid et al., 2019).

Korangi district is the largest industrial region in Karachi, Pakistan, and faces major environmental challenges, such as rapid urbanization and pollution (NASA Earth Observatory, 2013). The district has a mixed development of industrial, commercial, and residential zones. The area's growth has led to pressure on local infrastructure and natural resources, causing environmental degradation. The number of households in Korangi increased from 437,932 in 2017 to 493,504 in 2023 Figure 1 (a). Both urbanization and industrial growth increased rapidly in the region, with Figure 1 (b) depicting the population growth from 1990 to 2020. We can see that population growth increased very fast from 2010 onwards creating immense pressure for more energy.

Figure 1

Objectives

The objectives of this study included: 1. To mark the installed solar panels on high-resolution images for the years 2017 and 2023; 2. To collect Ground Control Points (GCPs) of reading collection spots (sample collection points) around the installed solar panels area and assess the solar potential study area; 3. To estimate pollution level (VOCs, NO2, CH4 and SO2) within

the range of electric power plant; 4. To analyze the pollution levels in industrial and nonindustrial sectors for the years 2017 and 2023; and 5. To assess solar potential in Korangi.

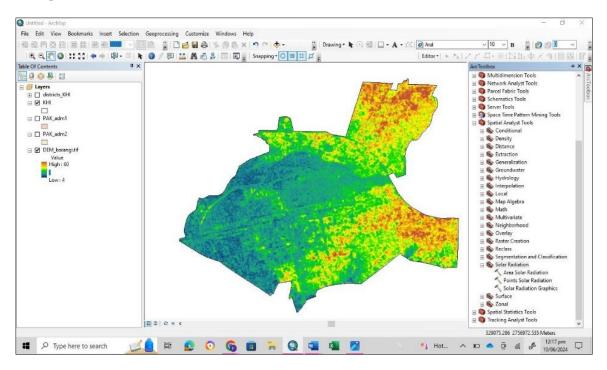

MATERIAL AND METHODS

Google Earth Pro

By using Google Earth Pro (Kausar et al., 2022), solar panels' location in industries has been identified for the years 2017 and 2023. In addition, Objects Based Identification (OBI) have been conducted (Kausar et al., 2023a; Kausar et al., 2024; Taylor & Lovell, 2012).

Figure 2

ArcMap-Area Solar Radiation Tool is used in the Arc toolbox

This image has been generated by authors.

ArcMap 10.8 has been used for further analyses i.e., calculation of solar radiation, for this, the area solar radiation tool has been used that is present in the Arc toolbox, to set the analysis parameters into the geographical location and configure the setting of atmospheric effects (Figure 2). Finally, the tool was used to generate solar radiation maps by adding DEM data (year 2014). Therefore, a digital elevation model has been executed to get the final product.

Pollution Data

The pollution data was acquired and assessed through solar panel identification. Several parameters i.e., CO₂, CO, PM¹⁰ PM^{2.5}, VOCs, SO₂, and NO₂ were monitored through different instruments (Table 1).

Air quality, Forensics Detector			
Air Quality Humidity Detector to record fine particulate matter			

GIS Analyses (Interpolation)

The data was collected from 95 sites, of which 54 are solar panel sites and the remaining 41 are commercial and residential sites. The distribution allowed us to observe and compare the levels of pollution in areas with solar panels versus typical residential and commercial areas. The Inverse Distance Weighting (IDW) interpolation method was selected. IDW method is considered efficient in assessing values at unsampled locations based on nearby measurements. It aligns with our data's spatial characteristics and validation outcomes (Kausar et al., 2022). Surfaces are generated through the IDW method by using ArcGIS for air quality data. IDW will help to analyze data and for the identification of hotspots of pollutants i.e.CO2, CO, PM^{2.5,} and PM¹⁰ IDW surfaces have also been generated for VOCs, NO2, SO₂, and CH4 pollutants at the power plants (Figure 3).

The data evaluation framework of the study area

RESULTS AND DISCUSSIONS

There are 54 industries in which solar panels have been installed. The locations of solar panels

that have been found through satellite imagery, in 2023, have been captured in Figure 4.

Comparative Satellite Image Analysis for 2017 and 2023- Assessing Solar Panel Integration

Through the detailed Google Earth Pro observation, we can see that there is limited occurrence in both residential and non-industrial sectors in 2017 of solar panels in the Korangi area. Comparatibely, by 2023 there is integration of solar panels, which are more prevalent in industrial areas compared to residential areas (Figure 5(a) and 5(b)).

This

Assessment of Solar Radiation Potential by Using Remote Sensing

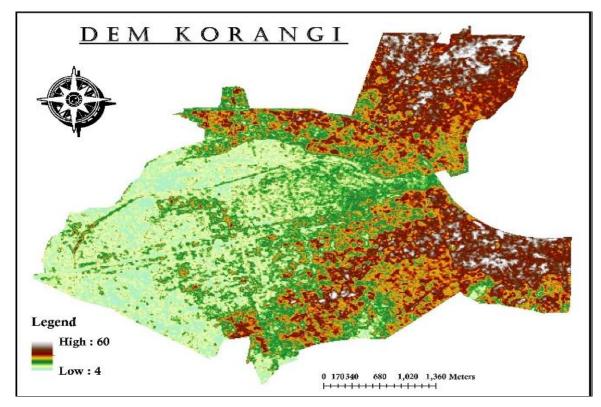

In Korangi, the topographical variation is revealed through DEM data (Figure 6) with elevation ranging from 4 meters to 60 meters above sea level. The difference highlights (56 meters) the area's diverse landscape that influences local hydrological patterns and urban infrastructure (Figure 7). In Figure 7 the radiation shows within a day in WH/m². Generally, average daily solar radiation values in the world ranges between 4000 to 7000 WH/m²/day or 4 to 7 W/m² (National Renewable Energy Laboratory, 2024). Karachi has potential maximum solar radiation levels of 7,330 WH/m², and that thus the city has immense potential for solar generation (Tutiempo Network, 2024). Korangi is situated in the southern part of the country, approximately 24.8 degrees north of the equator at latitude. That is relatively close to the equator, contributing to the high level of solar radiation and warm climate. The major product of this area is 5000-7000 WH/m²/day, it is considered a favorable radiation for solar panels or energy production (Figure 7).

image has been generated by authors

Significant variation has been quantified by zonal analysis through ArcMap in daily solar radiation values across different UCs in Korangi, Karachi. The highest recorded radiation is 15,568 WH/m², while the mean values range from 4,466 WH/m² in Morio Khan Goth to 5,467 WH/m² in Zaman Town. The (STD) values implying the alterability in daily solar radiation, range from 1,981 in Burmee Colony to 2,569 in Muslimabad. Other UCs such as Zaman Town, Awami Colony, Sherabad Colony, and Korangi 33 also portray comparatively high solar radiation values, with means around 5,400 WH/m². Most of the UCs in Korangi receive substantial solar radiation, with means generally around 5,000 WH/m²/day.

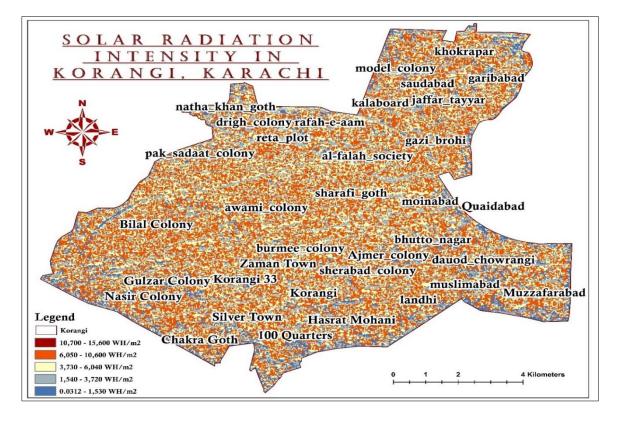

Figure 6

This image has been generated by authors

Table 2 shows the statistical values of different commercial areas in district Korangi. Karachi. Industrial areas such as textile and clothing manufacturing, Places for Packaging Agriculture and Food Products, Timber, Furniture, Paper, and Printing industries show higher radiation, as they receive more sunlight throughout the day (Figure 8) and have taller buildings in the area (Teunissen et al., 2021). Other places like mosques and other religious places (based on observation surveys) and small commercial places nearby all have fewer receivers in value compared to industries. Industrial facilities with optimal solar gain, are often designed to maximize sunlight exposure, with fewer obstructions such as tall buildings nearby whereas mosques and smaller commercial structures may not prioritize such orientation, consequently receiving less sunlight absorption. (Soufiane et al., 2019). But still, radiation exceeds the

typical average, indicating excellent conditions for solar energy production in Korangi. This suggests that solar panels in this area could generate a significant amount of electricity.

Korangi Pollution Assessment:

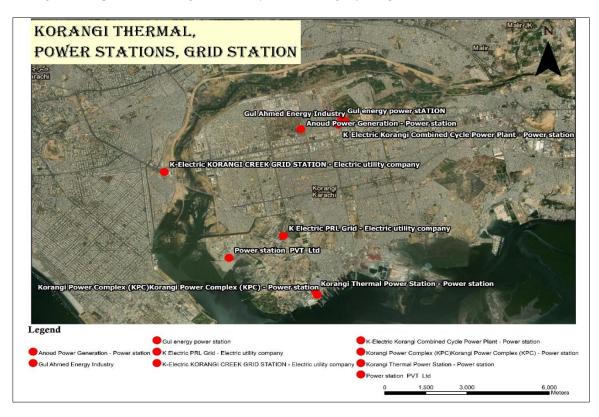

Air quality hazard zones

By assessing the 2023 data, it is observed that most of Korangi's Air Quality is restored, and the reason is the installation of solar panels and the conversion of power-generated resources.

Further study of power (electricity) generating plants has been conducted to validate this (Figure 9). Gather SO₂ ppm data of Korangi that clearly shows where electric power stations such as k Electric Korangi Creek, KPC, have higher SO2, around 88.5 μ g/m³ to 96 μ g/m³. In addition, nearby areas, specifically residential areas are affected. On the contrary, industrial Korangi regions have a lower ratio because Solar panels do not emit SO₂, so the use of solar panels in some areas has helped to reduce the overall levels of SO₂. A thorough study on the burden of respiratory diseases and cardiovascular to SO₂ exposure in Iran found that the highest occurrence of SO₂ causes deaths due to cardiovascular diseases was 0.080 μ g/m³ (Rabiei et al., 2020). This indicates that Korangi SO2 level contributes to the increased rates of heart failure arrhythmias, and other cardiovascular problems among locals.

Figure 9

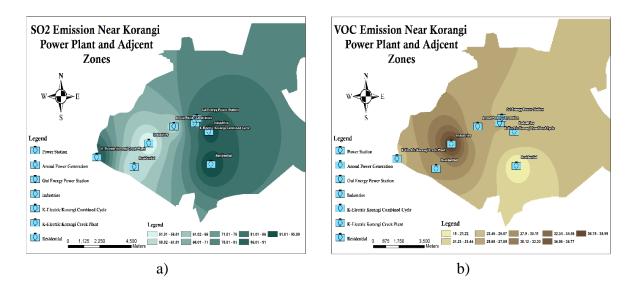

Korangi thermal power stations, grid station by satellite image of Google Earth Pro

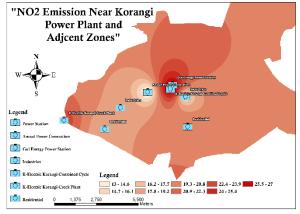

This image has been generated by authors

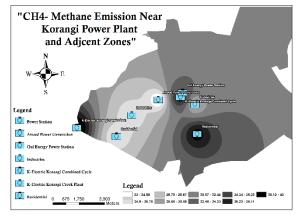

Volatile Organic Compounds (VOCs) are emitted from various sources, including power plants. To generate electricity, coal, oil, and natural gas combustion can release VOCs into the atmosphere (Figure 10). By assessing residential and industrial impact, places near industries are less polluted compared to where electric power plants and stations exist. The adjacent areas are also affected by pollution, which has a variety of harmful effects on human health. When fossil fuels such as coal, oil, gas, or diesel are burned at high temperatures, they emit nitrogen dioxide, a gashouse pollutant (Karakosta et al., 2021). Nitrogen dioxide can harm the human respiratory tract and make people more susceptible to respiratory infections and asthma. There was moderate evidence that short-term exposure to NO₂, even at mean values below 50 μ g/m³, both increased hospital admissions and mortality (Gillespie-Bennett et al., 2010).

Chronic lung disease can be caused by long-term exposure to high levels of nitrogen dioxide. Contact with pollutants such as particulate matter (PM), sulfur dioxide (SO2), and nitrogen oxides (NOx) can lead to chronic respiratory conditions, including asthma, chronic bronchitis, and reduced lung function (Hayat et al., 2023). Korangi Electric Power generation is near a residential area and in industries where employees regularly come from different places and have regular exposure. NO₂ was also found around the power station (Figure 10), and the reading reached 25.4 ppm. Though CH₄ is also found in Korangi, the source region is along the power station located in a residential area, followed by the K-Electric Creek plant and, once again, around Power station (Figure 10). The fine particulate material PM 1 is spread around the western zone. Three main power plants are in contagious condition: Residential Power Station, K-Electric Korangi Creek, and around the Power generation plant (Figure 10).

Comparative Assessment of Pollutants in Korangi-Karachi.

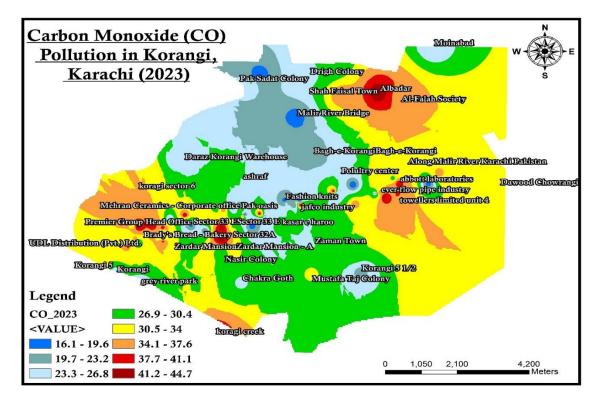

In comparison for years 2017 and 2023, it has been observed that a large region of Korangi faced a high level of contamination. The highest reading in 2017 was up to 20 ppm, while in 2023, it rose to 44.7 ppm. However, after critical examination (Figure 11) CO concentrations have arisen. At the same time, in 2023, the CO reading is much higher but concentrated only along some sources (Figure 11). Therefore, the extent becomes shortened, but the occurrence particularly becomes more concentrated. In the year 2017 (Figure 11), carbon dioxide gas emissions were recorded at Drigh Colony with the highest rate of emission i.e., 295.4, and the range extends till Bagh Korangi with the reading up to 258, Pak-Saadat Colony, again the loop of highest contamination is found in Abbott Laboratories, Toweller limited, and Jamia Dar Uloom, then along the pipeline industry and adjacent industries, while Mustafa Taj Colony and Chakra Got were also highest contamination area.

The emission of Carbon dioxide in Korangi will be reduced in 2023 (Figure 11), and the range of the CO₂-affected regions will be reduced from the areas before the study year (2017). Nevertheless, now contamination is confined along the industrial belt non-contagious but linear sources can easily be identified. Bagh e Korangi is still the hotspot like before. Also, Cui and colleagues (2019) reported that China is the major provider of global CO₂ releases; more than a quarter of the world's total CO₂ is from China due to fossil fuel combustion and cement production. Figure 12 (a) Carbon footprints in the industrial area of Korangi, Karachi. The maximum carbon was detected. Meanwhile, the CO₂ emissions from these ten industrial production developments displayed a fast rise before 2014 and varied from 2014 to 2018. The maximum emission was detected in the northern, central, and eastern parts of the Korangi district in 2023. **Figure 11** (*a*) Carbon Monoxide in 2017 b) Carbon Monoxide in 2023 Korangi, Karachi

These images have been generated by authors

Figure 13 (a &b) indicates the PM 2.5 concentration in Korangi Karachi. PM^{2.5} are lighterweight fine particles containing a diameter of 2.5 micrometers that are emitted from industries. A high level of PM^{2.5} was observed in 2017 on the western side of Korangi. While a decline has been observed since 2017, it is not much of a great share. No substantial decrease was observed during the past five years. Therefore, the installation of solar panels does not control PM^{2.5} efficiently. Korangi does not reflect major changes in pollutant declination for identification, the industrial zone has been digitized and analyzed closely.

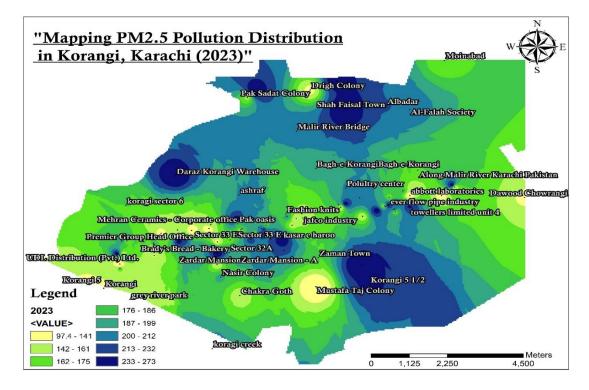

Figure 13(c) & (d) depicts the concentration of PM¹⁰ in the study area. In 2017, the areas of western Korangi experienced a high level of PM¹⁰ pollutants as compared to 2023. PM^{2.5} still exists in the environment but is now concentrated along the Mustafa Taj. These locations are not found in the industrial zone i.e. Daraz Korangi warehouse, Grey River Park, Shah Faisal, Korangi Sector 5 Korangi Creek are not found in the industrial region. In 2023 the concentration of PM 10 was found more as compared to 2017. The maximum hotspot areas are in western Korangi.

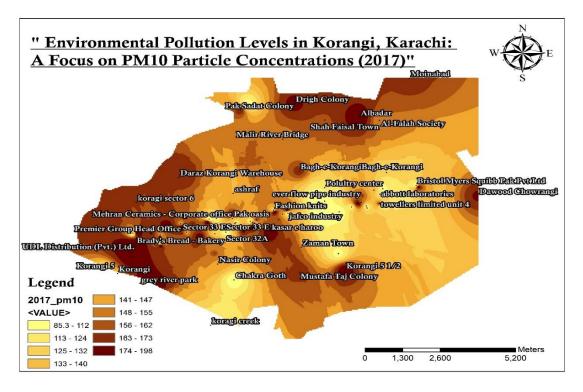

Figure 14 depicts that the hotspots of PM^{2.5}concentration are more in industrial areas where solar panels are not installed, or fewer solar panels are in the suburbs. At these hot spots, PM ^{2.5} level reached up to 256 ppm. Kausar, (2023b) reported that PM2.5 level around 256 ppm is considered as very unhealthy air quality. Son and colleagues (2020) revealed that the negative influences of airborne particulate matter (PM) on solar PV power generation should be considered in policymaking on target solar power generation in Korea and in states with high PM releases.

Monitoring PM 2.5 levels and Solar panel integration

This image has been generated by authors

CONCLUDING RECOMMENDATIONS

Korangi displays significant potential for solar energy, with daily radiation values ranging from 4,466 WH/m² to 15,568 WH/m² across different urban centers. Industrial areas like textile and food packaging industries receive higher radiation due to fewer obstructions, making them ideal for solar energy installations. Overall, the region's high solar radiation levels suggest substantial opportunities for solar energy development, especially in areas with optimal sunlight exposure.

After installing solar panels, CO, PM ¹⁰, and PM^{2.5} have been notably reduced in the Korangi environment. There are 54 locations where solar panels are installed within five years. Though the CO concentration is much higher (44.7) in 2023 than 20 in 2017, the change has been recorded in the form of spread. Earlier, the range over the land of Korangi was higher. Concentration is high, but certain spots and ranges over the land are limited. The extent of

PM¹⁰ and PM^{2.5} is also delimited in certain places. Concentration level is the main issue, as before. These source regions are Daraz Korangi warehouse, Grey River Park, Shah Faisal, Korangi Sector 5 Korangi Creek, and Mustafa Taj. By comparison between 2017 and 2023, the level of PM^{2.5} observed in 2017 was higher in the western side of Korangi. A decline has been observed since 2017, but it is not very significant.

PM^{2.5} are lighter-weight fine particles containing a diameter of 2.5 micrometers that are emitted from industries. In five years, the decline of the particulate is not much higher. Therefore, the installation of solar panels does not control PM^{2.5} efficiently. In the year 2017, carbon dioxide gas emissions were recorded at Drigh Colony with the highest rate of emission, i.e., 295.4, and the range extends till Bagh Korangi with the reading up to 258. Again the loop of highest contamination is found in Abbott Laboratories, Toweller Limited and Jamia Dar Uloom, and then along the pipeline industry and adjacent industries; while Mustafa Taj Colony and Chakra Got were also found to have highest contamination. It was expected that the emission of carbon dioxide in Korangi will be reduced in 2023, and the range of the CO2affected regions will be reduced from the areas before 2017. But now contamination is confined along the industrial belt, and non-contagious but linear sources can easily be identified. Bagh e Korangi is still the hotspot like before.

Implementing solar panels gives a way to live in a clean environment. Korangi is one of the main industrial sectors in Karachi and a source of income for many Karachiites; therefore, it is an important sector in terms of production and revenue generation, but a clean environment for a healthy lifestyle and the industry's labor workplace is essential. Since the Industrial Revolution, human beings have been in the race to make money at every cost, which has impacted the environment adversely. Air Quality Hazard zones are found along the areas of conventional power generating plants, as can be seen in the case of Korangi, Karachi. A sustainable approach is urgently needed to generate energy with lower impact on the environment. This is possible if both the industrial and residential sectors adopt the implementation of solar panels strategy and cost-effective technology to reduce and mitigate environmental pollution as well as save electricity bills in times of rising inflation. Many people remain unaware of solar energy's potential for environmental benefits and cost savings. This research aimed to help advocate for a reduced reliance on fossil fuels and mitigate greenhouse gas emissions. Such integration of renewable energy contributes to energy security and supports global climate commitments (Kabir et al., 2018).
